I prodotti indicati per il trattamento della disfunzione erettile, incluso il sildenafil, devono essere impiegati con cautela nei pazienti con deformazioni anatomiche del pene (es. angolazione, fibrosi cavernosa o malattia di Peyronie).

Treatment of erectile dysfunction in patients with Peyronie's disease using sildenafil citrate

LA Levine[1]* and KC Latchamsetty[1]

2002

Sildenafil ha consentito rapporti penetrativi al 70% dei pazienti trattati

Nessun paziente ha riportato un aumento del dolore penieno.

Lo studio non evidenzia che le erezioni e i coiti consentiti dall'utilizzo di sildenafil abbiano prodotto un peggioramento delle deformità del pene o la progressione della malattia

Non appare esistere nessuna controindicazione all'utilizzo di sildenafil dal momento che rappresenta la terapia per la disfunzione erettile meno invasiva e più conveniente per i paziente affetti da malattia di Peyronie.

SCHEDE TECNICHE

SILDENAFIL, VARDENAFIL, AVANAFIL

I prodotti indicati per il trattamento della disfunzione erettile, incluso il sildenafil, devono essere impiegati con cautela nei pazienti con deformazioni anatomiche del pene (es. angolazione, fibrosi cavernosa o malattia di Peyronie).

TADALAFIL

Deve essere impiegato con cautela nei pazienti con deformazioni anatomiche del pene (es. angolazione, fibrosi cavernosa o malattia di Peyronie).

4.3.1.7 Phosphodiesterase type 5 inhibitors

The rationale for the use of phosphodiesterase type 5 inhibitors (PDE5I) in Peyronie's disease comes from animal studies showing that they can reduce the collagen/smooth muscle and collagen III/I ratios and increase the apoptotic index in the Peyronie's disease-like plaque (64). In a retrospective controlled study, daily tadalafil (2.5 mg for 6 months) resulted in statistically significant ($p < 0.05$) resolution of septal scar in 69% of patients compared to 10% in the control group (no treatment). However, this study included patients with isolated septal scars without evidence of penile deformity (65). Therefore, no recommendation can be given for PDE5I in patients with Peyronie's disease.

CURRENT SURGICAL MANAGEMENT OF SEVERE PEYRONIE'S DISEASE

Sava V. Perovic† and Rados P. Djinovic[1].

Serbian Academy of Sciences and Arts. Belgrade. Serbia
[1]School of Medicine. University of Belgrade. Serbia.

Postoperative physiotherapy

Daily PDE5 inhibitors are prescribed for 3-4 weeks starting 2-3 days after surgery in order to induce erections and increase penile blood flow. Patients are advised to use of penile stretching device approximately 2-3 weeks postoperatively and vacuum device 1-2 weeks later to prevent graft shrinkage and consequent penile shortening and re-curvature. Physiotherapy was applied for 4-6 months after surgery.

We also advised using of vacuum device in patients with penile prosthesis implantation.

SEXUAL REHABILITATION AFTER PENILE RECONSTRUCTIVE SURGERY

ese patients, is two-fold:

e penis (anti-fibrotic action).
h the pre-operative situation and age of
-pathological mechanisms of secondary
avernosal bodies is mandatory in order

to avoid fibrotic processes. The steps to rehabilitation should be commenced approximately 25-30 days after the surgical treatment.

Treatment of ED has been revolutionized with the introduction of PDE5 inhibitors (PDE5i) and has paved the way for the rehabilitation concept in patients submitted to penile and prostatic surgery. Phosphodiesterase-5 (PDE5) is the enzyme responsible for catabolism of cGMP (cyclic monophosphate guanosine) produced in the smooth muscle fibre cells following their activation triggered by nitrogen monoxide. Administration of PDE5 inhibitors (PDE5i) is important in patients with ED in order to improve not only erectile function, but also systemic endothelial function. Furthermore, as demonstrated in numerous studies, it is possible to use chronic treatment with PDE5i, which have been shown to be more effective than *on-demand* treatments in improving this parameter (De Sousa, 2002; Rosano, 2005; Aversa, 2007; Sommer, 2005; Caretta, 2005). Pharmacological treatment in sexual rehabilitation following penile surgery has, furthermore, been found to be better accepted by the patients themselves inasmuch as it is non-invasive. Besides sildenafil, other agents with the same mechanism of action (tadalafil, vardenafil) are equally as efficacious. Tadalafil, in particular, presents certain pharmacological characteristics (long half-life) making it potentially the drug of choice in the rehabilitation phase. Suppression of the TGF β1-mediated collagen synthesis, especially at smooth muscle cell level, is the patho-physiological mechanism upon which the rehabilitative function of the inhibitors is based. Good condition of the nerves is, however, necessary, in order

Postoperative Care and Rehabilitation

Following surgery, postoperative rehabilitation is recommended to enhance recovery of erectile function. Massage and stretch therapy, is performed by grasping the glans penis and pulling it gently and repeatedly away from the body while also gently massaging the graft area. This is initiated 2 weeks after surgery and performed twice a day for 4 weeks. It is advised that the patient's partner get involved in the rehabilitation process to lessen the anxiety associated with the resumption of sexual activity for both partners. Bedtime phosphodiesterase inhibitors have been recommended to begin 7–10 days after surgery and to be maintained for 6 weeks, in order to enhance nocturnal erections, stretch the tissue, encourage nourishment of the graft [159], and possibly reduce the risk of postoperative ED. Finally, the use of external penile traction therapy has been noted to reduce postoperative penile shortening for patients who have undergone either placation or grafting procedures. Traction is initiated 2–3 weeks postoperatively when the circumcising incision has adequately healed and is performed on a daily basis for a minimum of 2–8 hours for 3 months [181].

2014

4.4.2 *Penile lengthening procedures*

Tunical incision, preferably with grafting, offers an excellent surgical option for men with curvatures over 60° as well as patients with an hourglass deformity and good erectile function that are willing to risk a higher rate of postoperative erectile dysfunction (139). The presence of pre-operative erectile dysfunction, the use of larger grafts, age more than 60 years, and ventral curvature are considered poor prognostic factors for functional outcome after grafting surgery (106). Although the risk for penile shortening is significantly less compared to the Nesbit or plication procedures, it is still an issue and patients must be informed accordingly (104). The use of a penile extender device on an 8- to 12-hour daily regimen has been advocated as an effective and safe way to the loss of penile length in patients operated on for Peyronie's disease (140).

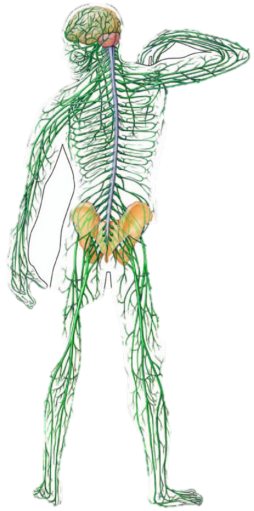
& NO & PDE5i

• è stato dimostrato che le PDE5 sono espresse nel SNC
• in seguito a somministrazione di sildenafil sono descritti effetti nel SNC negli uomini
• i donatori di NO aumentano i livelli di cGMP nell'ipotalamo, e l'infusione di NO nell'ambiente extracellulare all'interno della MPOA dei ratti induce le erezioni e stimola il comportamento sessuale
• NO riduce le efferenze simpatiche alla periferia attraverso un meccanismo dipendente dal cGMP o attraverso interazioni con altri neurotrasmettitori
• la somministrazione intratecale di sildenafil nei ratti aumenta i livelli di NO e cGMP nella MPOA
• la riduzione del tono adrenergico mediata dall'attività del NO è in relazione con l'inibizione dell'eiaculazione
• la microiniezione di inibitori delle NOS riduce la latenza alla prima eiaculazione



& NO & PDE5i

• NO e i donatori di NO inibiscono l'emissione del liquido seminale nei ratti
• gli inibitori di NO riducono la latenza eiaculatoria nei ratti
• l'innervazione mediata da NO e l'attività delle NOS sono state rilevate nei vasi deferenti, vescicole seminali, prostata e uretra
• l'attività delle PDE5 è stata rilevata nei vasi deferenti, vescicole seminali, prostata
• il sildenafil inibisce la trasmissione degli impulsi adrenergici nelle vescicole seminali umane
• il sildenafil ha un effetto inibitorio diretto sull'attività contrattile delle vescicole seminali

Guidelines on Male Sexual Dysfunction:

update 3/2013

Erectile dysfunction and premature ejaculation

K. Hatzimouratidis (chair), I. Eardley, F. Giuliano,
D. Hatzichristou, I. Moncada, A. Salonia, Y. Vardi, E. Wespes

4.8.6.1 Phosphodiesterase type 5 inhibitors

There is only one well-designed, randomized, double-blind, placebo-controlled study comparing sildenafil to placebo (40). Although IELT was not significantly improved, sildenafil increased confidence, the perception of ejaculatory control and overall sexual satisfaction, reduced anxiety and decreased the refractory time to achieve a second erection after ejaculation.

On-demand treatment of PE	**LE**	**GR**
PDE5 inhibitors	3	C

International Society for Sexual Medicine

Summary of recommended pharmacological treatments for premature ejaculation

Drug	Daily dose/ as needed	Dose	IELT fold increase	Side effects	Status	Level of evidence
Oral therapies						
Dapoxetine	As needed	30-60 mg	2.5-3	- Nausea - Diarrhea - Headache - Dizziness	Approved in some countries	1a
Paroxetine	Daily dose	10-40 mg	8	- Fatigue - Yawning - Nausea - Diarrhea - Perspiration - Decreased sexual desire - Erectile dysfunction	Off label	1a
Clomipramine	Daily dose	12.5-50 mg	6		Off label	1a
Sertraline	Daily dose	50-200 mg	5		Off label	1a
Fluoxetine	Daily dose	20-40 mg	5		Off label	1a
Citralopam	Daily dose	20-40 mg	2		Off label	1a
Paroxetine	Daily dose for 30 days and then as needed	10-40 mg	11.6		Off label	1a
Paroxetine	As needed	10-40 mg	1.4		Off label	1a
Clomipramine	As needed	12.5-50 mg	4		Off label	1a
Topical therapy						
Lidocaine/ prilocaine	As needed	25 mg/gm lidocaine 25 mg/gm prilocaine	4-6	- Penile numbness - Partner genital numbness - Skin irritation - Erectile dysfunction	Off label	1b

&
PDE5i

IPOTESI PATOGENETICHE di EP da DE

§ Risposta comportamentale conscia o inconscia alla D.E.

§ Associazione con ansia da prestazione (ipertono adrenergico)

H.S. Kaplan, 1989 – B. Zilbergeld, 1992

L'ipertono adrenergico attiva l'emissione seminale destabilizzando il controllo del riflesso eiaculatorio

J. Volpe, 1982 – W. Wiliam, 1984

L'ipertono adrenergico riduce la percezione dei segnali prodromici dell'orgasmo

HS. Kaplan, 1989 – B. Zilbergeld, 1992

Può non essere una vera E.P., ma un'eiaculazione da iperstimolazione in caso di reiterati e protratti tentativi di indurre l'erezione

CONCLUSIONI

Il trattamento con tadalafil 10 o 20 mg al bisogno è associato a un significativo miglioramento delle funzioni eiaculatoria e orgasmica (vs placebo) indipendentemente dal grado di DE, disfunzione eiaculatoria o orgasmica.

D. Hatzichristou, I. Moncada, A. Salonia, Y. Vardi, E. Wespes

update
3/2013

Clinical diagnosis of premature ejaculation based on patient +/- partner history

- Time to ejaculation (IELT)
- Perceived degree of ejaculatory control
- Degree of bother/distress
- Onset and duration of PE
- Psychosocial/relationship issues
- Medical history
- Physical examination

Treatment of premature ejaculation

Patient counselling/education
Discussion of treatment options
If PE is secondary to ED, treat ED first or concomitantly

- Pharmacotherapy (recommended as first-line treatment option in lifelong PE)
  - Dapoxetine for on-demand use (the only approved drug for PE)
  - Off-label treatments include chronic daily use of antidepressants (SSRIs or clomipramine) and topical anaesthetics or oral tramadol on demand
- Behavioural therapy, includes stop/start technique, squeeze and sensate focus
- Combination treatment

- anorgasmia

EIACULAZIONE RITARDATA/ANEIACULAZIONE

DSM-IV-TR
Persistente o ricorrente ritardo, o assenza, dell'orgasmo in seguito a una normale fase di eccitazione durante l'attività sessuale che il clinico, considerando l'età del soggetto, giudica adeguata in termini di qualità, intensità e durata. Il disturbo causa considerevole distress o difficoltà interpersonali.

WHO 2nd Consultation on Sexual Dysfunction
Persistente o ricorrente difficoltà, ritardo o impossibilità di raggiungere l'orgasmo in seguito a sufficiente stimolazione sessuale, che causa un personale distress

EIACULAZIONE RITARDATA/ANEIACULAZIONE

Non esistono criteri precisi per stabilire quando un paziente è affetto da eiaculazione ritardata

Considerato che la maggior parte degli uomini sessualmente attivi eiacula in un intervallo compreso tra 4 e 10 minuti, il clinico può assumere che gli uomini che presentano latenze di oltre 25 minuti e che riferiscono distress, oppure gli uomini che cessano l'attività sessuale per esaurimento o irritazione, presentino una eiaculazione ritardata.

EIACULAZIONE RITARDATA/ANEIACULAZIONE

Prevalenza 1.5/1000
Non superiore al 3%

25% lifelong
75% acquisita

Nella maggior parte dei casi: nessuna evidenza di chiara eziologia somatica

CAUSE	
Psychogenic	Inhibited ejaculation
Congenital	Mullerian duct cyst Wolfian duct abnormality Prune belly syndrome
Anatomic Causes	Transurethral resection of prostate Bladder neck incision
Neurogenic Causes	Diabetic autonomic neuropathy Spinal cord injury Radical cystectomy or prostatectomy Proctocolectomy Bilateral sympathectomy Abdominal aortic aneurysmectomy Para-aortic lympthadenectomy
Infective	Urethritis Genito–urinary tuberculosis Schistosomiasis
Endocrine	Hypogonadism Hypothyroidism
Medication	Alpha-methyl dopa Thiazide diuretics Tricyclic and SSRI antidepressants Phenothiazine Alcohol abuse

PDE5i & EP

NO nell'SNC e SNP agisce aumentando la latenza eiaculatoria

PDE5i sono stati valutati per un potenziale trattamento dei disturbi eiaculatori, soprattutto l'EP

Sildenafil è il PDE5i più studiato per la terapia dell'EP

Efficacia PDE5i da soli o associati a SSRI per EP lifelong: bassi livelli di evidenza

PDE5i sembrano potenziare effetto degli SSRI

PDE5i + dapoxetina: associazione sicura

LG:	EP lifelong	basso grado di raccomandazione
	EP +DE	PDE5i prima scelta

Per ora scarse informazioni
